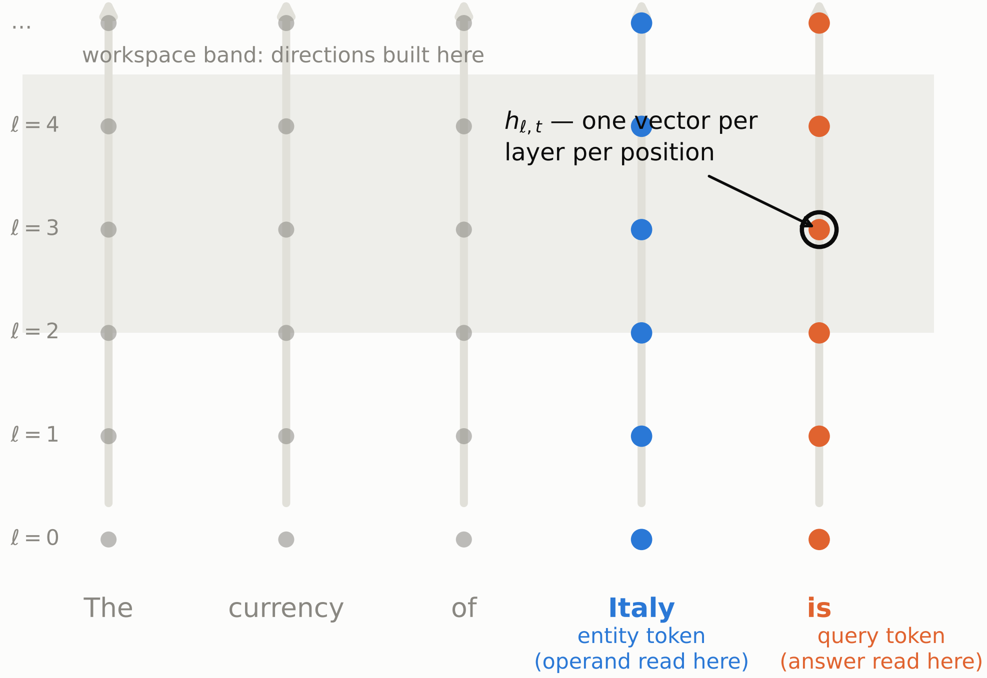
The state is a grid: layers × positions



One object, applied three ways

at each band layer ℓ, average the query-token states:

$$v_\ell(\mathrm{op}) = \mathrm{mean}_o\,[\,h_{\ell,-1}(o,\mathrm{op}) - \mathrm{mean}_k\, h_{\ell,-1}(o,k)\,]$$

≡ the ANOVA operator main effect $b_\ell(\mathrm{op})$ (verified: dev. 10^{-8})

steer add $\alpha\,(v_\ell(B) - v_\ell(A))$ at the query token → margin flips; generates at calibrated α

compose replace $h_{\ell,-1}$ with $\mu_\ell + a_\ell(o) + b_\ell(k)$ → generates at the clean ceiling

decode classify / ANOVA the same states → factorization, layer profiles

Prompt → token × layer grid of residual states → per-layer operator direction by averaging at the query token → applied by addition (steering), by replacement (composition), or read out (ANOVA).
